Abstract: In current years there has been an increasing interest in the study of sparse representation of signals. Using an over complete glossary that contains prototype signal-atoms, signals are described by sparse linear combinations of these atoms. Recognition of persons by means of biometric description is an important technology in the society, because biometric identifiers cannot be shared and they intrinsically characterize the individual's bodily distinctiveness. Among several biometric recognition technologies, fingerprint compression is very popular for personal identification. One more fingerprint compression algorithm based on sparse representation using K-SVD algorithm is introduced. In the algorithm, First we construct a dictionary for predefined fingerprint photocopy patches. For a new given fingerprint images, suggest its patches according to the dictionary by computing l^0 -minimization by MP method and then quantize and encode the representation. This paper compares dissimilar compression standards like JPEG, JPEG-2000, WSQ, K-SVDetc. The paper show that this is effective compared with several competing compression techniques particularly at high compression ratios.

Keywords: Compression, sparse representation, JPEG, JPEG 2000, WSO, K-SVD.

I. INTRODUCTION

In the world today we are identified by the various Targeted at fingerprint images, there are special biometric characteristics such as fingerprint recognition and in this paper we explain the fingerprint recognition based on sparse representation. Because in recent years there will be growing interest in the field of sparse representations of signals. Applications that use sparse representation are many that include compression, regularization in converse problems, feature extraction, more. Among many biometric recognition and technologies, fingerprint compression is very popular for personal identification due to the uniqueness, universality, collectability and invariance [1].

Large volumes of fingerprints are collected together and stored daily in a wide range of applications, including forensics, access control and fingerprint square measure evident from the information of Federal Bureau of Investigation (FBI). Large volume of data requires the large amount of memory. Fingerprint compression is a key technique to solve the problem. Compared with general normal images the fingerprint images contain simpler configuration. They are only composed of ridges and valleys. In the local regions, they seem to be the same. Therefore, to solve these two problems the pre-processing, pre-aligned the whole image is sliced into square and nonoverlapping small patches.

Generally, compression technologies can be classed into lossless and lossy. The 8×8 small block of images. This transform has been used in JPEG [4]. The JPEG compression theme has several benefits like simplicity, catholicity and accessibility. However, it has a bad performance at low bit-rates mainly due to the underlying block-based DCT format. For this motive, as early as 1995, the JPEGcommittee begins to develop a new wavelet-based compression for still images, especially JPEG 2000[5].

compression algorithms. The most common is Wavelet Scalar Quantization (WSQ)[7]. It became the FBI standard for the compression of 500 dpi fingerprint images. Motivated by the WSQ algorithm, a few wavelet packet based fingerprint compression schemes such as Contourlet Transform (CT) have been developed. But, these algorithms have a common shortcoming namely, without the ability of knowledge. The fingerprint images can't be compacted well now. They will not be compressed well later. In this paper, a innovative approach based on sparse representation is given [8]. The proposed method has the ability by updating the dictionary. The effects on actual fingerprint matching or recognition are not examined. In this paper, we will take it into contemplation. In most Automatic Fingerprint identification System (AFIS), the main feature used to match two fingerprint images are minutiae (ridges endings and bifurcations). Therefore, the difference of the minutiae among pre- and postcompression is considered in the paper.

II. LITERATURE SURVEY

In this section, we describe the various image compression techniques and also we compare the proposed method with existing fingerprint compression algorithms like JPEG, JPEG-2000, WSQ, K-SVD etc. Generally, compression technologies can be classed into lossless and lossy.

Lossless compression is type of image а compression algorithms that allows the original data to be perfectly reconstructed from the compressed data. Typical image file formats of lossless compression are like PNG or GIF; It is also often used as a component within lossy data compression technologies. Lossless

INTERNATIONAL JOURNAL OF INNOVATIVE RESEARCH IN ELECTRICAL. ELECTRONICS. INSTRUMENTATION AND CONTROL ENGINEERING Vol. 4. Issue 2. February 2016

compression is used where it is essential that the original only improve compression performance over JPEG but and the decompressed data be identical, or where also adding features such as scalability and edit ability. deviations from the original data could be deleterious. Lossless compression methods may be classified according to the type of data they are designed to compress.

Lossy compression technologies usually transform an image into another domain, quantize and encode its coefficients. lossy compression is the type of image encoding methods that uses inexact approximations to represent the content. These methods are used to reduce data size for storage, handling, and transmit content. The amount of data reduction achievable using lossy compression is often much higher than through lossless techniques. In lossy transform codes, samples of image are taken, chopped into small segments, transformed into a new basis space, and quantized. The resulting quantized values are then encoded using entropy coding. There are transform-based image compression methods have been implicitly researched and some principles have appeared. Two most common options of transformation are the Discrete Cosine Transform (DCT) [2] and the Discrete Wavelet Transform (DWT)[3].

A. JPEG

JPEG is of а commonly used technique lossy compression for digital images, particularly for those images which are produced by digital photography. Image files that use JPEG compression are generally called "JPEG files", and are stored in variants of the JIF image format. The term "JPEG" is an acronym for the Joint Photographic Experts Group. The DCT-based encoder is use for compression of a stream of 8×8 small block of images. This alteration has been used in JPEG [4]. The JPEG compression technique has some benefits such as simplicity, universality and availability. However, it has a bad performance at low bit-rates because of the essential block-based DCT scheme. For this reason, as early as 1995, the JPEG-committee start to develop a new waveletbased compression model for still images, namely JPEG 2000[5][6].

B. JPEG 2000

JPEG 2000 (JP2) is a type of image compression and coding system. It was created by the Joint Photographic Experts Group in 2000 with the purpose of suppressing their original discrete cosine transform based JPEG standard (created in 1992) with a newly designed, waveletbased method. There is a modest increase in compression performance of JPEG 2000 compared to JPEG; the main advantage of JPEG 2000 is the significant elasticity of the code stream. The DWT-based algorithms consist of three steps: a DWT computation of the normalized image, quantization of the DWT coefficients and lossless coding of the quantized coefficients. The detail can be found in [7] [12]and. Compared with JPEG, JPEG 2000 provides many qualities that maintain scalable and interactive access to large-sized image. In addition it allows extraction of different resolutions, pixel fidelities, regions of interest, components etc. There are some other DWTbased algorithms, such as Set Partitioning in Hierarchical We evaluate this algorithm and express its results both on Trees (SPIHT) Algorithm. The aim of JPEG 2000 is not synthetic tests and in applications on real image data.

The improvement of JPEG 2000's in compression performance relative to the original JPEG standard is actually rather modest and should not ordinarily be the primary suggestion for evaluating the design. Very low and very high compression rates are supported in JPEG 2000. The capability of the design to handle a very large range of effective bit rates is one of the strengths of JPEG 2000. For example, to decrease the number of bits for a image below a certain amount, the advisable thing to do with the image before encoding it. That is unnecessary when using JPEG 2000, because JPEG 2000 automatically does this through its multiresolution decomposition structure.

C. SPIHT

Several other algorithms that use DWT includes set partitioning in hierarchical trees (SPIHT) algorithms The most efficient algorithm in the area of image compression is the Set Partitioning in Hierarchical Trees (SPIHT) [13]. It uses a sub-band coder which produces a pyramid structure where an image is decomposed sequentially by applying power complementary low pass and high pass filters and then decimating the resulting images. These filters are one-dimensional filters that are applied in cascade (row then column) to an image whereby creating the four-way decomposition

D. WSQ

The Wavelet Scalar Quantization algorithm (WSQ) is a compression algorithm used for gray scale fingerprint images. It is based on wavelet theory and has become a standard for the replace and storage of fingerprint images. WSQ was developed by the Federal Bureau of Investigation (FBI)[7] for the compression of 500 dpi fingerprint images. The WSQ compression technique developed by the FBI and alternative entities was designed to compress fingerprint pictures between ratios of 10:1 and 20:1.

At these compression ratios, sufficient friction ridge and pore detail is maintained for the needs of identification, by fingerprint matching hardware and by human latent fingerprint examiners. This compression method is chosen over standard compression method like JPEG because at the same compression ratios WSQ doesn't present the "blocking artifacts" and failure of fine-scale features that are not suitable for identification in financial environments and criminal justice.

E. K-SVD

K-means clustering process K-SVD is an iterative method that alternates between sparse coding of the examples based on the existing dictionary and a process of updating the dictionary atoms to better fit the data [9]. The update of the dictionary columns is grouped with an update of the sparse representations, thereby accelerating convergence. The K-SVD algorithm is expandable and can work with any pursuit method (e.g., basis pursuit, FOCUSS, or matching pursuit).

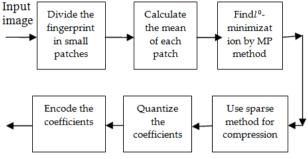

INTERNATIONAL JOURNAL OF INNOVATIVE RESEARCH IN ELECTRICAL, ELECTRONICS, INSTRUMENTATION AND CONTROL ENGINEERING Vol. 4, Issue 2, February 2016

III. PROPOSED SYSTEM IMPLEMENTATION

In this section, we give the details about how to use K-SVD algorithm for fingerprint compression based onspares representation. The part includes construction of the dictionary, compression of a given fingerprint, quantization and coding and analysis of the algorithm complexity as shown in figure (1).

Obtaining an overcomplete dictionary from a set of fingerprint patches allows us to represent them as a sparse linear combination of dictionary atoms.

Compressed data

Fig.1. Proposed System Block Diagram.

A. Construction of the Dictionary

In this paper, the dictionary will be assembled in three ways. First, we construct a training set. Then, the dictionary is obtained from the set. Cut the whole fingerprint image in fixed size square patches as in figure (2).

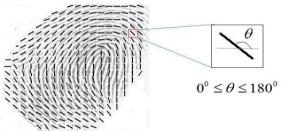

Fig.2.A fingerprint image with its fixed square patches

The specific process is as follows: create a base matrix whose columns characterize features of the fingerprint images, referring the matrix dictionary whose columns are called atoms; for a whole fingerprint, divide it into small blocks called patches whose number of pixels are identical to the dimension of the atoms use the method of sparse representation to obtain the coefficients then quantize the coefficients; last encode the coefficients and other related information using lossless coding methods. Greedy algorithm is used to construct training sample.

Then the dictionary is obtained by the following steps.

- The first patch is added to the dictionary, which is initially empty.
- Then we check whether the next patch is adequately similar to all patches in the dictionary. If yes, then next patch is tested; otherwise, the patch is added into the dictionary. Here, the similarity measure between two patches is calculated by solving the optimization problem (1).

$$S(P_1, P_2) = \min_{t} \left\| \frac{P_1}{\|P_1\|_F^2} - t * \frac{P_2}{\|P_2\|_F^2} \right\|_F^2$$
(1)

Where $\| \bullet \|_{F}^{2}$ is the Frobenius norm. P_{1} and P_{2} are the corresponding matrices of two patches. t, a parameter of the optimization problem (1), is a scaling factor.

• Repeat the second step until all patches have been tested.

In the preceding paragraphs, it is mentioned that the dictionary will be constructed in three ways the first is select the patches at random and arrange them as columns of the dictionary (Random-SR). The second is to select patches according to orientations called Orientation-SR, The third is to prepare the dictionary by K-SVD method (K-SVD-SR in short)[9]. The dictionary is obtained by solving an optimization problem (4). Y is the training patches, A is the dictionary, X are the coefficients and X_i is the i th column of X. The dictionary for the K-SVD algorithm is constructed as follows.

Given A = $[a_{1,a_2,\ldots,\ldots,a_N}] \in \mathbb{R}^{(M*N)}$, any new sample y $\in \mathbb{R}^{(M*1)}$ canbe represented as a sparse linear combination of few columns from the dictionary A, as shown in formula (2). This is the only prior knowledge about the dictionary in our algorithm. Later, we will see the property can be ensured by constructing the dictionary properly.

$$Y = AX \tag{2}$$

Where
$$y \in R^{M \times 1}$$
, $A \in R^{M \times N}$, and $x = [x_1, x_2, ..., x_N]^T \in R^{N \times 1}$.

If M < N. and A is a full-rank matrix, an infinite number of solutions are available for the illustration of problem, hence constraints on the solution must be set. The solution with the fewest number of nonzero coefficients is definitely an appealing representation. A proper solution can be obtained by solving the following sparsest optimization problem:

$$(\ell^0): \min \|x\|_0 \quad s.t. \quad Ax = y$$
 (3)

Where $\| \bullet \|_0$ is thel⁰- norm, counting the nonzero entries of a vector.Solution of the optimization problem is very sparse if $\| x \|_0 \ll N$. The notation $\| x \|_0$ counts the nonzero entries in x actually it is not a norm. However, without uncertainty, we still call it ℓ^0 -norm. In fact, the compression of y can be achieved by compressing X. To solve the optimization problem ℓ^0 we should compute the coefficients matrix X using MP method, which guarantees that the coefficient Vector X_i has no more than T non-zero elements. Then, update each dictionary element based on the singular value decomposition (SVD) method.

$$\min_{A,X} \left\| Y - AX \right\|_{F}^{2} \qquad s.t. \ \forall i \left\| X_{i} \right\|_{0} < T$$
(4)

In the following paper, the three kinds of dictionaries will be compared.

INTERNATIONAL JOURNAL OF INNOVATIVE RESEARCH IN FLECTRICAL, FLECTRONICS, INSTRUMENTATION AND CONTROL ENGINEERING Vol. 4, Issue 2, February 2016

B. Compression of a Given Fingerprint

For the fingerprint compression based on sparse representation, the size of patches and the size of the dictionary are the most important parameters. The size of patches has a direct impact on compression efficiency. The larger the size is, the higher the efficiency is. However, to 6. Output the compressed stream. represent an arbitrary patch well, the size of the dictionary needs to be sufficiently large. This causes more computational complexity. There for the proper size of patch should be chosen. So far, there is no good way to estimate the parameter. For our proposed system implementation we can chose the 12×12, 16×16 and 20×20 sizes of patches. There are two reasons that the size 8×8 is not tested. The patches of this size are too small to contain the structure of fingerprints and it's difficult to compress such small patches at high compression ratios. In addition, to make the patches fit the dictionary superior, the mean of each patch is to be calculated and subtracted from the patch. After that, calculate the sparse l^0 representation for each patch by solving the minimisation problem. Those coefficients whose absolute values are less than a specified threshold are treated as zero. Improves the compression ratio. For every patch, four kinds of information require to be recorded. They are the mean value, the number regarding how many atoms to

use, the coefficients and their locations. The tests show that many image patches require few coefficients. Consequently, compared with the use of a fixed number of coefficients, the method reduces the coding complexity and improves the compression ratio

C. Quantization and Coding

Entropy coding of the atom number of each patch, the mean value of each patch, the coefficients and the indexes is calculated by static arithmetic coders [10]. The atom number of each patch is individually coded. The mean [1] value of each patch is also individually coded. The quantization of coefficients is achieve using the Lloyd algorithm [11], The first coefficient of each block is quantized by means of a larger number of bits than other coefficients i.e. in proposed system the first coefficient is [4] quantized with 6 bits and all other coefficients are quantized with 4 bits and entropy-coded with a separate arithmetic coder. The model for the indexes is estimated by using the source statistics achieved off-line from the ^[6] training set. The first index as well as other indexes is coded by the same arithmetic encoder.

D. Testing of the Algorithm Complexity

The algorithm includes two parts that is the training process and the compression process. Because the training process is off-line, simply the complexity of compression process is analyzed.

Algorithm 1 Algorithm for fingerprint compression based on sparse representation

- 1. For a given fingerprint cut it into small patches.
- 2. For each patch its mean is calculated and subtracted from the patch.
- 3. For each patch, solve the l^0 -minimization problem by MP method.
- 4. Those coefficients whose absolute values are less than a

given threshold are treated as zero. Record the remaining coefficients as well as their locations.

- 5. Encode the atom number of each patch, the mean value of each patch, and indexes; quantize and encode the coefficients.

Algorithm 1 summaries the entire compression process. The compressed stream doesn't include the dictionary and the information about the models. It consists exclusively of the encoding of the atom number of each patch, the mean value of each patch, the coefficients and also the indexes. In practice, only the compressed stream needs to be transmitted to restore the fingerprint. In both encoder as well as the decoder, the dictionary, the quantization tables of the coefficients and the statistic tables for arithmetic coding need to be stored.

IV. CONCLUSION

The different compression techniques are adapted to compress the fingerprint images are studied and compared their Performance especially at high compression ratios.New compression algorithm based on sparse representation in introduced. Due to the block-by-block processing mechanism, however, the algorithm has higher complexities. The paper shows that the K-SVD algorithm for fingerprint compression based on sparse representation is more efficient than other compression technique such as JPEG, JPEG2000,WSQ. One of the main problem in developing compression algorithms for fingerprints resides in the need for protection of the minutiae which are used in the identification. Our algorithm can be able to hold most of the minutiae forcefully during the compression and reconstruction.
